

DESCRIPTION

GPS RECEIVER AND RELATED METHOD AND APPARATUS

5 The present invention relates to a GPS receiver comprising a GPS antenna and a GPS RF front-end including an analogue to digital converter for sampling received GPS signals; and a processor for outputting the GPS signal samples.

10 The present invention further relates to a corresponding method of providing a position fix comprising the steps of receiving from a GPS receiver GPS signal samples and processing the GPS signal samples to determine a position fix; and to a computer program, computer-readable storage medium and apparatus for the same.

15 Article "Real-time software radio architectures for GPS receivers" by Akos et al. (GPS World, July 2001) discloses "software GPS" in which much GPS signal processing is accomplished by means of a programmable micro-processor or digital signal processor as opposed to analogue or discrete hardwires components. As illustrated in figure 2 of this article, a simplified GPS
20 receiver is provided consisting of a GPS antenna and GPS RF front-end for GPS signal pre-processing (including filtering, amplification and frequency down-conversion) and analogue to digital conversion. GPS signal samples outputted from the GPS receiver are then fed in to a modern PC or laptop running appropriate GPS signal processing software for processing the GPS
25 signals to determine a position fix. The authors of this article have contemplated the GPS receiver to be a "plug-in" module, i.e. a "dongle" type device, which because of its simple architecture could be manufactured cheaply, thereby facilitating widespread adoption. And, of course, the GPS signal processing software which resides on the PC is inherently cheap to
30 replicate.

 Whatever specific GPS receiver architecture and GPS signal processing software configuration are adopted, it would be of course be

expected that the output of the GPS receiver is compatible with the GPS signal processing software. In other words, since the attributes of the interface between the GPS receiver and GPS signal processing software are known, one or both would be designed with the other in mind. For example, the GPS
5 signal processing software might have been configured to handle GPS signal samples of format, rate and resolution outputted by the GPS receiver.

In accordance with the present invention, there is provided a GPS receiver of the aforementioned type in which the processor outputs (especially
10 to an external device) the GPS signal samples together with ancillary information either directly or indirectly describing characteristics of the GPS signal samples and / or the GPS signals contained therein.

Also provided in accordance with the present invention is a method of providing a position fix comprising the steps of: receiving from a GPS receiver
15 GPS signal samples together with ancillary information describing characteristics of the GPS signal samples and / or the GPS signals contained therein and processing the GPS signal samples using the ancillary information to determine a position fix; and a computer program, computer-readable storage medium and apparatus for the same.

20 The inventors have realised that future software GPS systems may not necessarily have their GPS receivers (i.e. the GPS antenna and GPS RF front-end portion) and their GPS signal processing software designed with each other in mind. The present invention provides a mechanism by which GPS signal processing software receiving the ancillary information can establish
25 and then adapt to the characteristics of a particular GPS receiver's output. This enables particular GPS signal processing software to process signals outputted from a variety of GPS receivers, and which may even have been designed and / or manufactured by different companies.

30 The present invention will now be described, by way of example only, with reference to the accompanying figure which shows, schematically, a

laptop PC connected to a GPS receiver, both operating in accordance with the present invention.

Referring to the accompanying figure, the laptop PC is connected via a
5 USB PC port and corresponding cable to the GPS receiver 10 which consists
of a GPS RF front-end Rx and a GPS antenna. Whilst the GPS receiver could
have been a "dongle" type device thereby omitting the cable, the cable
facilitates positioning of the GPS receiver (including the antenna) in a
prominent position, thereby increasing the chances of acquiring GPS signals.
10 For example, one might place the GPS receiver near a window if operating in
doors.

When operative, the GPS receiver receives NAVSTAR SPS GPS
signals through its antenna and pre-process them, typically by passive
bandpass filtering in order to minimise out-of-band RF interference,
15 preamplification, down conversion to an intermediate frequency (IF) and
analogue to digital conversion. The resultant GPS signal samples contain the
IF signal which remains modulated, still containing all the information from the
available satellites.

In accordance with the present invention, the GPS signal samples are
20 outputted from the GPS receiver via the USB link into PC memory (not shown)
with ancillary information describing characteristics of the GPS signal samples
and / or the GPS signals contained therein.

Using laptop PC based GPS signal processing software and the
ancillary information, the GPS signal samples are then processed so that GPS
25 signals may be acquired for the purpose of deriving pseudorange information from
which the position of the PC can be determined using conventional navigation
algorithms. Such GPS signal acquisition and pseudorange processing is well
known, for example, see GPS Principles and Applications (Editor, Kaplan)
ISBN 0-89006-793-7 Artech House.

The ancillary information may include the following:

Information relating to the GPS receiver itself:

- 5 ▪ type and / or identity of the GPS receiver. If the GPS signal processing software can access a database mapping the type and / or identity of a GPS receiver to characteristics of GPS signal samples outputted that particular GPS receiver and / or the GPS signals that particular GPS receiver is used to receive, then the type and / or identity of the GPS receiver can be indirectly used by such
- 10 GPS signal processing software to process the GPS signal samples.

Information relating to the GPS signal received by the GPS receiver:

- 15 ▪ type and / or identity of the received GPS signal. A particular GPS receiver may be designed to receive different GPS signals and / or operate in one or a plurality of operating modes as, for example, directly selected by a user using user input means of the GPS receiver.
- 20 ▪ received GPS signal(s) format
- received GPS signal(s) centre frequency
- received GPS signal(s) bandwidth

Information relating to the GPS samples outputted by the GPS receiver:

- 25 ▪ outputted GPS signal carrier frequency. The received GPS signal will typically be down converted to an intermediate frequency (IF) by the GPS receiver.
- outputted GPS signal bandwidth. This ought to corresponding to filtering done by the GPS receiver.
- outputted GPS signal sample format
- outputted GPS signal sample rate
- 30 ▪ outputted GPS signal sample resolution

- image sign; that is, whether an increase in the frequency of the received GPS signal results in either an increase or decrease in the outputted GPS signal sample carrier frequency
- oscillator type and / or oscillator stability parameters; for example, whether the GPS receiver's oscillator has temperature compensation and if it does, accuracy parameters, and if not, error parameters.
- antenna type; for example, indicating the effective beam pattern.

Where appropriate, the ancillary information may also include information relating to the accuracy of any of the above.

It is likely there will be a requirement for at least some initialisation between the laptop PC and the GPS receiver, for example, triggered by the laptop's operating system detecting the presence of the GPS receiver. This may include an exchange of ancillary information prior to streaming GPS signal samples in to the laptop PC so enable the GPS software to correctly receive the data and to allow the GPS signal processing software to select a preferred configuration.

Whilst the present invention has been illustrated in the context of a laptop PC, it is of course equally applicable to other apparatus able to support GPS signal processing software and to which a GPS receiver according to the present invention can be connected. For example, the invention may be employed with mobile devices such as PDAs and telephone; or generally stationary objects such as a TVs or TV set-top boxes.

Also, whilst the connection between the GPS receiver and the GPS signal processing software is entirely wired in the above example, it could conceivably involve a wireless link.

Furthermore, the GPS receiver shown in the accompanying figure may be provided with user input means with which a user may directly select one of a plurality of operating modes. For example, the user may change something relating to the GPS signal received by the GPS receiver such as at what centre frequency the GPS receiver is expecting to receive GPS signals should there

be more than one possible frequency for target signals. In an alternative example, the user may change something relating to the GPS samples outputted by the GPS receiver such as at what sample rate or resolution the GPS signal samples are outputted.

5 As stated above, information relating to the GPS receiver's oscillator may be outputted by the GPS receiver to assist the laptop PC based GPS signal processing software. Oscillators generally have a stated operating frequency range corresponding to manufacturing tolerances, but it likely that the actual operating frequency which falls within this range is very stable. If
10 such an oscillator in the GPS receiver is individually calibrated, this calibration information or a derivative thereof (e.g. the subsequent change in GPS signal sample output frequency) can be provided to the GPS signal processing software. The GPS signal processing software can actually perform the calibration itself by analysing the GPS receivers measurement of the
15 frequency of received GPS signals. Once a position fix has been determined, the frequency of the received GPS signals can be determined authoritatively and hence the GPS receivers measurement error quantified. This error may then be uploaded to the GPS receiver and stored in say a flash memory so that subsequently, the GPS receiver can output this calibration information to
20 assist GPS signal processing software performing a position fix.

Finally, whilst the invention has been described in the context of NAVSTAR GPS, the all weather, spaced based navigation system developed and currently operated by the US Department of Defense, it will be appreciated that the invention is equally applicable to other global positioning systems
25 including GLONASS and Galileo and hybrids thereof.
